Pandas

```
1. Vista de los datos(4.1.1)
```

- 2. Selección(4.1.2)
- 3. Setting(4.1.1))
- 4. Missing values(4.1.1)
- 5. Operaciones (4.2.1)
- 6. Unión de dataframe (4.1.1)
- 7. Grouping (4.1.1 / 4.1.4)
- 8. Reshaping (4.1.1)
- 9. Time Series
- 10. Categoricals
- 11. Plotting

Contiene dos tipos de estructuras:

- Series: una matriz etiquetada unidimensional que contiene datos de cualquier tipo como números enteros, cadenas, objetos Python, etc.
- **Dataframe**: una estructura de datos bidimensional que contiene datos como una matriz bidimensional o una tabla con filas y columnas.

```

Resultados Nota_3:

Varianza

Se calcula la cuasi-varianza:

```
S^2 = \frac{\sum_{i=1}^n \{i=1\}(x_i-X)^2}{n-1}
```

```
In [75]: var_1 = df["notas_1"].var()
    var_1
```

Out[75]: 14.5

```
In [76]: var_2 = df["notas_2"].var()
    var_2
```

```
In [77]: var_3 = df["notas_3"].var()
    var_3
```

Out[77]: 13.1555555555555

Si queremos calcular la varianza, utilizamos el argumento ddof=0. El denominador en la fórmula será entonces n-ddof=0:

```
In [78]: var_1 = df["notas_1"].var(ddof=0)
    var_1
```

Out[78]: 13.05

Desviación típica

En python, utilizamos el método .std() para calcular la cuasi-desviación típica. Para calcular la desviación típica, nuevamente utilizamos ddof=0. \$\$ S^=\sqrt{S^2} \$\$

```
In [79]: std_1 = df["notas_1"].std()
std_1
```

Out[79]: 3.8078865529319543

```
In [80]: std_2 = df["notas_2"].std()
std_2
```

Out[80]: 2.8982753492378874

```
In [81]: std_3 = df["notas_3"].std()
std_3
```

Out[81]: 3.6270588023294517

Si queremos calcular la varianza, utilizamos el argumento ddof=0. El denominador en la fórmula será entonces n-ddof=0:

```
In [82]: std_1 = df["notas_1"].std(ddof=0)
    std_1
```

Out[82]: 3.6124783736376886

Se puede añadir un parámetro que se llama how , donde se especifica el tipo de unión de los dataframes, para ello, nos basamos en la siguiente tabla para relacionarlos con los comandos SQL:

Merge method	SQL Join Name	Description
left	LEFT OUTER JOIN	Use keys from left frame only
right	RIGHT OUTER JOIN	Use keys from right frame only
outer	FULL OUTER JOIN	Use union of keys from both frames
inner	INNER JOIN	Use intersection of keys from both frames
cross	CROSS JOIN	Create the cartesian product of rows of both frames
new_setosa =	pd.merge(iris_medi	idas, new_species, how='left', on='Id')

Grouping

By "group by" we are referring to a process involving one or more of the following steps:

- Splitting the data into groups based on some criteria
- Applying a function to each group independently
- Combining the results into a data structure

Plotting

Pandas usa de manera interna matplotlib, simplemente importando la librería y pasando el dataframe a .plot() te genera el gráfico:

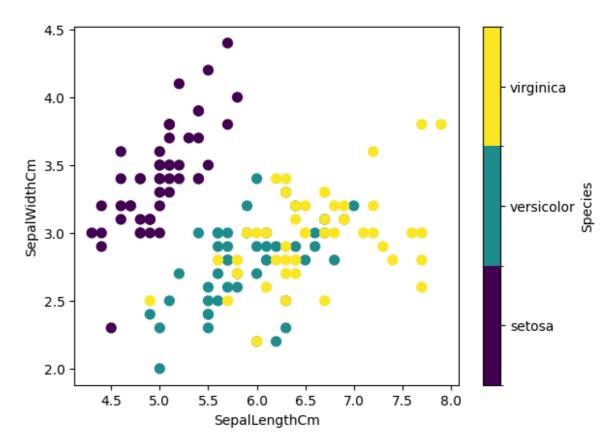

Out[299]: <Axes: >

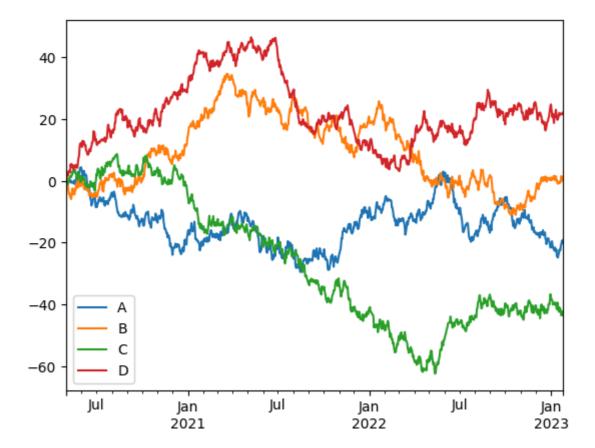

```
In [144... # c: variable categorica
    # cmap: escala de color
    # s: tamaño de los puntos

iris.plot.scatter(x='SepalLengthCm', y='SepalWidthCm', c='Species', cmap=
```

Out[144]: <Axes: xlabel='SepalLengthCm', ylabel='SepalWidthCm'>

Out[145]: <matplotlib.legend.Legend at 0x7a69e77f5ba0> <Figure size 640x480 with 0 Axes>

Numpy

- 1. Método array() (4.1.3))
- 2. Método arange())
- 3. Matrices básicas en numpy
- 4. Métodos random() / indices()-/-indices())
- 5. Réplicas o copias con numpy
- 6. Leer un archivo csv con el método loadtxt())
- 7. Modificación de matrices
- 8. Slicing
- 9. Comparacion entre Arrays
- **10.** Operaciones (4.1.3)
- 11. Matematical functions (4.1.3)

```
In [147... # pip install numpy

In [148... import numpy as np
```

Método array()

Un array puede formarse apartir de otras estructuras de Python como son listas o tuplas:

```
In [149... e = np.array([
       [1, 2],
       [3, 4],
```

```
[5, 6]
          ])
          е
Out[149]: array([[1, 2],
                   [3, 4],
                   [5, 6]])
In [150... len(e)
Out[150]: 3
In [151... e.shape
Out[151]: (3, 2)
In [152... e.size
Out[152]: 6
In [155... e[0]
Out[155]: array([1, 2])
In [156... for i in range(len(e)):
              # print(e[i])
              for j in range(len(e[i])):
                   print(e[i][j])
        1
        2
        3
        4
        5
In [157...
          ald = np.array((1, 5, 6))
          ald
Out[157]: array([1, 5, 6])
          Se puede añadir otro atributo que es dtype indicando de cuantos bytes consta el
          array:
In [158... np.array([127, 128, 129], dtype=np.int8)
```

```
/tmp/ipykernel_6411/2745257341.py:1: DeprecationWarning: NumPy will stop a
llowing conversion of out-of-bound Python integers to integer arrays. The
conversion of 128 to int8 will fail in the future.
For the old behavior, usually:
    np.array(value).astype(dtype)
will give the desired result (the cast overflows).
    np.array([127, 128, 129], dtype=np.int8)
/tmp/ipykernel_6411/2745257341.py:1: DeprecationWarning: NumPy will stop a
llowing conversion of out-of-bound Python integers to integer arrays. The
conversion of 129 to int8 will fail in the future.
For the old behavior, usually:
    np.array(value).astype(dtype)
will give the desired result (the cast overflows).
np.array([127, 128, 129], dtype=np.int8)
```

Out[158]: array([127, -128, -127], dtype=int8)

Representa enteros desde -128 a 127, arroja un error de fuera de rango.

Lo normal es que se formen arrays entre 32 o 64-bit de valores enteros o decimales:

```
In [160... a = np.array([2, 3, 4], dtype=np.uint32)
    print(a)
    b = np.array([5, 6, 7], dtype=np.uint32)
    print(b)
    c = a - b
    print(c)

[2 3 4]
    [5 6 7]
    [4294967293 4294967293 4294967293]

In [161... c_32 = a - b.astype(np.int32)
    c_32

Out[161]: array([-3, -3, -3])
```

El método .astype() convierte el array b en int32, en vez en uint32.

Podemos saber de que tipo de datos son mediante la función issubdtype():

```
In [163... d = np.dtype(np.int64)
    print(d)

# 1º Atributo es el array a testear y 2º Atributo el tipo que queremos co
    print(np.issubdtype(d, np.integer))
    print(np.issubdtype(d, np.floating))

int64
```

True False

Los tipos de datos pueden ser: boleanos (bool), enteros (int), enteros sin signo (uint), decimales (float) y complejos (complex).

También pueden ser: string numpy.str_ dtype (U character code), secuencia de bytes numpy.bytes_ (S character code), and arbitrary byte sequences, via numpy.void (V character code).

```
In [164... | np.array(["hello", "world"], dtype="S7").tobytes()
Out[164]: b'hello\x00\x00world\x00\x00'
```

Método arange().

Numeros dentro de un rango:

Generación de números con numpy en un rango

```
In [165...] a = np.arange(6)
Out[165]: array([0, 1, 2, 3, 4, 5])
In [166... type(a)
Out[166]: numpy.ndarray
          Formas de imprimir la información
```

```
In [173... print(a)
        [0 1 2 3 4 5]
In [168... for i in a:
               print(i)
        0
        1
        2
        3
        4
```

Longitud, forma, tamaño

```
In [169... a
Out[169]: array([0, 1, 2, 3, 4, 5])
In [170... len(a)
Out[170]: 6
In [171... a.shape

         # segunda columna: 16, 9, 4, 1.
         np.vander((1, 2, 3, 4), 4)
```

Matriz identidad multiplicada por un valor

Métodos zeros() / ones()

Matriz de todo 1

Matriz de todo 0

```
In [203...] 12 = np.zeros((6, 2))
         12
Out[203]: array([[0., 0.],
                  [0., 0.],
                  [0., 0.],
                  [0., 0.],
                  [0., 0.],
                  [0., 0.]])
In [204... np.zeros((2, 3, 2)) # Idem: a ones()
Out[204]: array([[[0., 0.],
                   [0., 0.],
                   [0., 0.]],
                  [[0., 0.],
                   [0., 0.],
                   [0., 0.]]])
         Metodos random() / indices()
         random() genera valores pseudoaletarios entre 0 y 1:
In [206... from numpy.random import default rng
         # 42: corresponde a seed
         # array de 2 filas x 3 columnas
         default rng(42). random((2,3))
Out[206]: array([[0.77395605, 0.43887844, 0.85859792],
                  [0.69736803, 0.09417735, 0.97562235]])
In [207... default_rng(42).random((2,3,2)) # idem a ones()
Out[207]: array([[[0.77395605, 0.43887844],
                   [0.85859792, 0.69736803],
                   [0.09417735, 0.97562235]],
                  [[0.7611397 , 0.78606431],
                   [0.12811363, 0.45038594],
                   [0.37079802, 0.92676499]]])
         indices(): genera una matriz de un conjunto de matrices:
In [208... # Matriz de 3 filas por 3 columnas:
         np.indices((3,3))
Out[208]: array([[[0, 0, 0],
                   [1, 1, 1],
                   [2, 2, 2]],
                  [[0, 1, 2],
                   [0, 1, 2],
                   [0, 1, 2]]])
```

Replicas o copias con numpy

```
In [209... a = np.array([1, 2, 3, 4, 5, 6])
b = a[:2]
b += 1
print('a =', a, '; b =', b)

a = [2 3 3 4 5 6]; b = [2 3]
```

El cambio realizado a b afecta en a en este caso es una réplica de a.

Ahora veamos que ocurre si usamos numpy.copy()

```
In [210... a = np.array([1, 2, 3, 4])
b = a[:2].copy()
b += 1
print('a = ', a, 'b = ', b)

a = [1 2 3 4] b = [2 3]
```

En este caso, a no se ve afectado por los cambios de b, ya que b es una copia de a.

```
In [211... | A = np.ones((2, 2))]
         print('A: \n', A)
         B = np.eye(2, 2)
         print('B: \n', B)
         C = np.zeros((2, 2))
         print('C: \n', C)
         D = np.diag((-3, -4))
         print('D: \n', D)
         a4d = np.block([[A, B], [C, D]])
         print('4D: \n', a4d)
        Α:
         [[1. 1.]]
         [1. 1.]]
        B:
         [[1. 0.]
         [0. 1.]]
        C:
         [[0. 0.]
         [0. 0.]]
        D:
         [[-3 0]
         [ 0 -4]]
        4D:
         [[1. 1. 1. 0.]
         [1. 1. 0. 1.]
         [ 0.
               0. -3. 0.]
               0. 0. -4.]]
```

np.block : crea la matriz resultante de: [[A, B], [C, D]]

Leer un archivo csv con el metodo loadtxt()

Modificacion de matrices

Matematical functions

Trigonometric functions

Description
Trigonometric sine, element-wise.
Cosine element-wise.
Compute tangent element-wise.
Inverse sine, element-wise.
Inverse sine, element-wise.
Trigonometric inverse cosine, element-wise.
Trigonometric inverse cosine, element-wise.
Trigonometric inverse tangent, element-wise.
Trigonometric inverse tangent, element-wise.
Given the "legs" of a right triangle, return its hypotenuse.
Convert angles from radians to degrees.
Convert angles from degrees to radians.

Rounding

Functions	Description
round(a[, decimals, out])	Evenly round to the given number of decimals.
around(a[, decimals, out])	Round an array to the given number of decimals.
rint(x, /[, out, where, casting, order,])	Round elements of the array to the nearest integer.
fix(x[, out])	Round to nearest integer towards zero.
floor(x, /[, out, where, casting, order,])	Return the floor of the input, element-wise.
ceil(x, /[, out, where, casting, order,])	Return the ceiling of the input, element-wise.

Functions	Description
trunc(x, /[, out, where, casting, order,])	Return the truncated value of the input, elementwise.

Sums, products, differences

Functions	Description
prod(a[, axis, dtype, out, keepdims,])	Return the product of array elements over a given axis.
sum(a[, axis, dtype, out, keepdims,])	Sum of array elements over a given axis.
nanprod(a[, axis, dtype, out, keepdims,])	Return the product of array elements over a given axis treating Not a Numbers (NaNs) as ones.
nansum(a[, axis, dtype, out, keepdims,])	Return the sum of array elements over a given axis treating Not a Numbers (NaNs) as zero.
cumprod(a[, axis, dtype, out])	Return the cumulative product of elements along a given axis.
cumsum(a[, axis, dtype, out])	Return the cumulative sum of the elements along a given axis.
gradient(f, *varargs[, axis, edge_order])	Return the gradient of an N-dimensional array.
cross(a, b[, axisa, axisb, axisc, axis])	Return the cross product of two (arrays of) vectors.

Arithmetic operations

Functions	Description
add(x1, x2, /[, out, where, casting, order,])	Add arguments element-wise.
$ \begin{array}{l} \text{reciprocal(x, /[, out, where, casting,} \\ \ldots]) \end{array} $	Return the reciprocal of the argument, element-wise.
positive(x, /[, out, where, casting, order,])	Numerical positive, element-wise.
negative(x, $/[$, out, where, casting, order,])	Numerical negative, element-wise.
multiply(x1, x2, /[, out, where, casting,])	Multiply arguments element-wise.
divide(x1, x2, /[, out, where, casting, \dots])	Divide arguments element-wise.
power(x1, x2, /[, out, where, casting,])	First array elements raised to powers from second array, element-wise.
pow(x1, x2, /[, out, where, casting, order,])	First array elements raised to powers from second array, element-wise.
subtract(x1, x2, /[, out, where, casting,])	Subtract arguments, element-wise.

Functions	Description
true_divide(x1, x2, /[, out, where,])	Divide arguments element-wise.
floor_divide(x1, x2, /[, out, where,])	Return the largest integer smaller or equal to the division of the inputs.
float_power(x1, x2, /[, out, where,])	First array elements raised to powers from second array, element-wise.
fmod(x1, x2, /[, out, where, casting,])	Returns the element-wise remainder of division.
mod(x1, x2, /[, out, where, casting, order,])	Returns the element-wise remainder of division.

Extrema finding

Functions	Description
maximum(x1, x2, /[, out, where, casting,])	Element-wise maximum of array elements.
max(a[, axis, out, keepdims, initial, where])	Return the maximum of an array or maximum along an axis.
minimum(x1, x2, /[, out, where, casting,])	Element-wise minimum of array elements.
min(a[, axis, out, keepdims, initial, where])	Return the minimum of an array or minimum along an axis.
